Objective For 26 patients with neonatal seizures, we designed a panel with 741 seizures related genes and performed targeted sequencing.

Methods The subjects were consisted of 26 neonatal convulsions with unknown cause. Among them, 18 (69.2%) were female and 8 (30.8%) were male. 741 genes coding regions capture was performed using the SureSelect Target Enrichment kit from Agilent. Results Overall, we identified 87,920 SNVs in 26 patients. Of the 1497 variants with unknown significant (VUS), 3 were nonsense variants, 3 were in splicing site, and 33 missense variants were predicted to be damage by SIFT and PolyPhen2. These 39 variants affected 32 genes were found in 19 probands. We identified pathogenic mutations in 7 cases (26.9%).

Conclusion The sequencing analysis of 741 seizures related genes was performed in 26 patients with neonatal convulsions. We identified pathogenic mutation in 6 cases (23.1%) which may contribute to the selection of specific medication treatment.

PO-0483c REVISED NICHD DEFINITION FOR BRONCHOPULMONARY DYSPLASIA (BPD) PREDICTS NEURODEVELOPMENTAL IMPAIRMENT (NDI) AT 2 YEARS CORRECTED AGE IN SINGAPORE

W Poon, J Yang, Neonatal and Developmental Medicine, Singapore General Hospital, Singapore, Singapore

10.1136/archdischild-2014-307384.1126

Aim To determine how well the revised NICHD criteria for bronchopulmonary dysplasia (BPD) predicts neurodevelopmental impairment (NDI) and growth impairment at 2 years corrected age (CA) in the contemporary era in a multi-ethnic Asian population.

Methods Longitudinal cohort study.

Setting Singapore General Hospital, a regional tertiary teaching hospital.

Participants Preterm infants with birthweight < 1250 grammes, admitted from Jan 1 2009 to Dec 31 2010 with BPD compared to no BPD.

Outcome measures Neurodevelopmental and growth outcomes. Further multiple logistic regression were performed on factors, particularly modifiable factors, associated with BPD, which may be associated with NDI.

Results Out of 72 infants who satisfied the inclusion, 60 survived the primary hospitalisation. 46 children (77% of survivors) returned for Bayley III at 2 years, and 44 completed the assessment. BPD children had significantly lower birthweight and were more likely to be from a multiple pregnancy, to require high frequency oscillatory ventilation, to have pneumothorax, hemodynamically significant PDA (HSPDA), nosocomial sepsis and pneumonia, longer duration of ventilation and oxygen. They were also more likely to have ROP and NEC, but not IVH. BPD children were more likely to have NDI (defined by cognitive, language or motor scores < 70) OR 6.3 (95% CI 1.1–36.7). No significant differences were found for growth parameters at 2 years CA. Multiple logistic regression revealed independent association of HSPDA with NDI.

Conclusion NICHD definition of BPD significantly predicts NDI at 2 years CA. HSPDA was independently associated with NDI.

PO-0483d PUNCTATE LESIONS ON MR IMAGES IN PRETERM INFANTS AT TERM CORRECTED AGE

1 A. Ederers, 1P Nongena, 1V Wardley, 1N Hayward, 1J Wurie, 1N Gonzalez-Cinca, 2D Azzopardi, 2S Counsell, 3M Rutherford, 3N Kennea, 4A. D. Edwards on behalf of the ePrime study, 1Paediatrics, Imperial College London, London, UK; 2Centre for the Developing Brain, Kings College London, London, UK; 3Neonatology, St George’s Healthcare NHS Trust, London, UK

10.1136/archdischild-2014-307384.1127

Introduction We studied Punctate Lesions detected by cerebral Magnetic Resonance (MR) in a large group of preterm infants recruited to the Evaluation of Preterm Imaging Programme (ePrime).

Methods We studied 511 of 2133 eligible infants cared for in 13 neonatal units including 5 Perinatal Centre. 254 were male and 84 from multiple pregnancies. Median (range) gestational age (GA) was 30 (23–32) weeks and birthweight 1270 (552–3160) g. T1 and T2 weighted MR images were obtained at 38–44 weeks GA in 479 and 44–60 weeks GA in 32 infants, and reported using conventional diagnostic criteria.

Results Neuroradiological analysis detected punctate lesions in 98 infants (19%), of whom 42 (8%) had more than 20 lesions. Preliminary analysis found no relation with more extreme prematurity, multiple pregnancy, birthweight, surfactant or antenatal steroid therapy, length of respiratory support or treatment for patent ductus arteriosus. No punctate lesions were reported on contemporaneous cranial ultrasonography, and 87/98 of those scans were reported as normal.

Conclusions Punctate lesions are common, of unclear aetiology, and not detected by ultrasonography.

PO-0483e NO NEUROPROTECTIVE EFFECTS OF CANNABIDIOL AFTER SEVERE HYPOXIA-ISCHEMIA IN NEWBORN PIGLETS

1HT Garbez, 1MU Huun, 2J Escobar, 3J Martinez Orgado, 4R Solberg, 4OD Saugstad. 1Department of Paediatric Research, Oslo University Hospital, Oslo, Norway; 2Research Unit, Health Research Institute Hospital La Fe, Valencia, Spain; 3Experimental Unit, Pediatic Department University Hospital Puenta de Hierro Majadahonda, Madrid, Spain

10.1136/archdischild-2014-307384.1128

Background and aim Hypothermia is limiting neurological sequelae after perinatal asphyxia. Still a significant number of infants have minimal effect of the treatment. Adjuvant neuroprotective strategies are therefore needed. In animal studies the phytocannabinoid Cannabidiol (CBD) has shown great promise as a
