Background and aims Neonatal thyrotoxicosis is a rare condition caused by the transplacental passage of thyroid stimulating immunoglobulins from mothers with Graves’ disease. We report a case of neonatal thyrotoxicosis with concurrent supraventricular tachycardia.

Case Report The female infant, who was born by caesarean section due to breech delivery and meconium in the amniotic fluid at 36 weeks of gestation, presented with tachycardia on day 7. Her heart rate was between 260–300 beats/minute, and electrocardiogram revealed ongoing supraventricular tachycardia. Sotalol was effective after two cardioversions in maintaining sinus rhythm. Our patient was diagnosed to have thyroid storm due to thyrotoxicosis. Intensive medical therapy was started with 10 mg/kg/day of propylthiouracil, 1 drop of Lugol’s iodine solution three times per day, 2 mg/kg/day propranolol, and 2 mg/kg/day of oral prednisolone. After the diagnosis of neonatal thyrotoxicosis, the mother in our case was found out to have hyperthyroidism with TSH: 0.035 mU/mL (normal: 0.35- 4.94). She was immediately started methimazole treatment.

Conclusions The purpose of presenting this patient is to emphasise the importance of prenatal care and follow-ups. Obstetricians, endocrinologists, and paediatricians need to work together for better management of Graves’ disease associated pregnancies.

PO-0485 CEREBRAL BLOOD FLOW AND OXYGENATION CHANGES FOLLOWING BLOOD TRANSFUSION IN PRETERM INFANTS

1J Banerjee, 2S Leung, 3N Aladangady, 1Department of Neonatology, Homerton University Hospital, London, UK; 2Department of Medical Physics and Bioengineering, University College London, London, UK

Background and aims We have shown blood transfusion (BT) significantly reduces cerebral blood flow and improves cerebral tissue oxygenation in preterm infants during the first week of life.1

Aim To study the effect of BT on cerebral blood flow and oxygenation during the 2nd to 4th week of life in preterm infants.

Methods Pre and post-BT Anterior Cerebral Artery (ACA) peak systolic velocity, mean velocity, resistance index (RI) and pulsatility index (PI), and Superior Vena Cava (SVC) flow were measured using Doppler USS. Pre, during and post-BT cerebral oxygenation were measured using Near Infra-Red Spectroscopy (NIRo 300).

Pre and post-BT measurements were compared by paired t-test using SPSS 22.0.

Results 21 preterm infants with median (range) gestational age of 25(23–30) weeks, birth weight 805(630–1250) grams, chronologic age 14(8–27) days and pre-BT Haemoglobin 10.3(7.7–12.2) g/dl were studied.
Pre-BT ACA peak systolic (0.37 m/s) and mean velocity (0.19 m/s) decreased significantly post-BT (0.32 and 0.16 respectively; p < 0.01). There was no significant change in RI (p = 0.57) and PI (p = 0.53) in the ACA and SVC flow (p = 0.16) post-BT.

The cerebral HbO2 increased significantly (mean difference 12.53 µM; p < 0.001) post-BT. The pre-BT mean cerebral tissue oxygenation index (TOI) (66.5%) increased significantly post-BT (73.6%; p < 0.001).

Conclusion The cerebral blood flow velocity decreased but there was no change in SVC flow volume; cerebral tissue oxygenation improved following BT during the 2nd to 4th week of life in preterm infants.

Background and aim The need for ligation of a patent ductus arteriosus with a haemodynamically significant left to right shunt (hPDA) on echocardiography remains controversial. Aim was to determine echocardiographic and clinical differences of preterms with hPDA after ibuprofen therapy who underwent ligation and those who had no further intervention.

Methods Echocardiographic and clinical parameters of preterms with hPDA (< 30 weeks of gestation) were retrieved for the "ligation group" before surgical ligation and for the "non-ligation group" after the last ibuprofen cycle. Recruitment criteria for hPDA were an enddiastolic maximal velocity of the left pulmonary artery (LPAdia) ≥ 0.2 m/s and/or a ratio of the left atrium/aorta (LA/Ao-ratio) ≥ 1.4. Preterms who died before ligation/ductal closure were excluded.

Results In 53 of 461 preterms a hPDA was still present after ibuprofen. Thirty-nine preterms were included to the "ligation-group", 14 to the "non-ligation group". Significant differences were detected for diastolic and systolic blood pressure, LPAdia, LA/Ao-ratio, stroke volume, backward flow in the aorta abdominales and the period until total enteral nutrition. Further differences were detected in airway support, hPDA flow patterns, gestational age, intraventricular haemorrhage and necrotising enterocolitis before and after ductal closure.

Conclusions The hPDA of the "ligation-group" was haemodynamically more relevant and preterms were more morbid than in the "non-ligation group". The observed differences reflect our policy of constraining the need for ligation a hPDA on echocardiography to selective ligation subject to both the severity of echocardiographic findings and the hPDA’s clinical impact.
