have an unfavourable outcome. Cortical, thalamic and WM tissue labels were generated by neonatal atlas-based automated segmentation of the T2-weighted images [1]. Tissue labels were propagated onto the diffusion maps. FA and MD values were determined. Linear regression was performed to assess the correlation between FA/MD and DQ. Estimation of unfavourable outcome with FA/MD in WM and GM was examined using receiver operating characteristic (ROC) analysis.

Results Following correction for multiple comparisons and age at scan significant correlation was found between DQ and FA in WM (p = 0.0002), and MD in thalami (p = 0.0002) and cortex (p = 0.005). ROC analysis to estimate unfavourable outcome showed large area under the curve (AUC) for FA in WM, than MD in GM (Figure and Table).

Conclusion These data show that FA in WM and MD in GM may be used as biomarkers of outcome following HIE.

**Conclusions** Treatment with DHA after severe neonatal hypoxia attenuates lipid peroxidation and brain damage in both grey- and white matter tissues. These novel findings add new knowledge on oxidative injury and points at a possible therapeutic intervention after perinatal asphyxia or severe hypoxia in both term and preterm babies.

**Background** Experimental studies suggest that melatonin is neuroprotective. Preterm infants are deprived of the normal intrauterine exposure to maternal melatonin and may benefit from supplementation to adult physiological levels.

**Aim** To prove that melatonin supplementation to adult concentrations decreases prematurity associated white matter injury assessed by tract based spatial statistics at term equivalent age.

**Methods** The study was a phase 2 exploratory; multi-centre double-blinded randomised placebo-controlled 2-arm trial, evaluating the neuroprotective effect of melatonin in preterm infants less than 31 weeks gestation. The 2 study drugs, melatonin (active) and normal saline (placebo) were given as an intravenous infusion once a day for 7 days starting by 48 h after birth. The dose of melatonin (0.1 mcg/kg/hr for 2 h) was derived from our previous pharmacokinetic study. Analysis was by intention to treat. Magnetic resonance imaging (MRI) was done at term corrected age. A 5% difference in the fractional anisotropy (FA) on MRI was taken as the primary endpoint.

**Results** Fifty-eight preterm infants participated in the study; 30 received melatonin and 28 received saline. Four babies died in each group. The 2 groups did not show any differences in demographic data or in the short term adverse events. Seventeen infants from the melatonin group and 19 from the placebo group had MR images which were analysed. There was no difference in the FA in the 2 groups.

**Conclusions** Melatonin supplementation to adult physiological levels during the first week after birth did not alter FA in the preterm white matter at term equivalent age.
