the fathering role, providing for the family, and balancing home life and work contributed to fathering being the “biggest job ever.” Fathers viewed fatherhood as an opportunity for personal growth and reflected on how their lives had changed since the arrival of their infant. Fathers in both groups liked the convenience of the home visits and the validation of their role as a father. Fathers in the intervention group liked the tailored feedback using the video-modelled play intervention. Health professionals need to consider the cognitive and emotional challenges experienced by fathers in their transition to parenthood and provide supports accordingly.

**THE ANXIETY LEVELS OF PARENTS OF PREMATURE BABIES AND RELATED FACTORS**

R Celen, F Arslan Tas. Pediatric Nursing, Selcuk University, Konya, Turkey

Background
Having a premature infant in the parent brings about anxiety.

Aims
A descriptive and correlational study was carried out to determine the levels of anxiety and associated factors of parents with premature infants.

Methods
The research was performed at five hospitals with Neonatal Intensive Care Unit (NICU) located in the city centre of Konya between March 1 and April 30, 2012. The sample group was comprised of 97 parents with premature infants. The “Parent And Baby Information Form” prepared by researchers and Spielberger’s “State and Permanent Anxiety Scale” was used for data collection. The data were evaluated in terms of number, percentage, mean, standard deviation, t-test, Mann Whitney U and Kruskall Wallis-test.

Results
The mean score of state anxiety of mothers was 40, 15 ± 11, 25 while that of fathers was 37, 32 ± 10, 87 and this difference was not statistically significant (p = 0.076). The mean permanent anxiety score of mothers was 44, 30 ± 8, 98 while that of fathers was 39, 45 ± 85, 58 and this difference was statistically advanced significant (p = 0.000). Current gestational week, feel sufficient condition related to baby care, current living situation anxiety about the baby care, counting the baby’s breathing and evaluation had a significant effect on the anxiety level of mothers (respectively p = 0.021, p = 0.004, p = 0.000, p = 0.028). Educational status, working, perceived income status and current living situation anxiety about the baby care was observed to have a significant effect on the anxiety level of fathers (respectively p = 0.012, p = 0.010, p = 0.016, p = 0.017).

Conclusions
It found that mothers and fathers of premature infants experienced mild level of anxiety.

**EVALUATING PRENATAL EDUCATION PROGRAMS: A NEW MEASURE AND OUTCOMES**

K Bergles, L Barker, J Churchill, S Horn, J Smith. Faculty of Nursing, University of Calgary, Calgary, Canada; Early Childhood Team, Alberta Health Services, Calgary, Canada; Antenatal and Perinatal Education, Alberta Health Services, Calgary, Canada

There is limited evidence of the effectiveness of prenatal education programs, due to the lack of reliable and valid measurement evaluation tools. The UpStart Parent Survey – Prenatal Version was developed as a brief retrospective-pretest/posttest evaluation tool designed to be administered electronically or on paper. The objectives of this study were to (1) conduct preliminary psychometric analysis of the UpStart Parent Survey – Prenatal Version, (2) determine outcomes of a prenatal education program, and (3) examine differences in scores between data collection methods, and mothers versus fathers. We recruited 277 expectant parents registered in a 6-week prenatal education program. Parents completed the survey at the end of the program using electronic tablets or paper copies. We uploaded electronic data to FluidSurveys, and imported into SPSS; data from paper copies were entered manually. Both the paper and electronic versions of the survey took a similar amount of time to enter/download, clean and analyse. Parents had mixed preference for electronic or paper versions of the survey, indicating provision of both options as desirable. The UpStart Parent Survey – Prenatal Version is internally consistent with Cronbach’s alphas of ≥0.89 for each scale. Parents demonstrated significantly increased knowledge and parenting experiences, p <0.001; satisfaction with the program was high. There were no significant differences in pre- or post-test scores for knowledge or experience scales whether paper or electronic surveys were used, or mothers or fathers completed the survey. The UpStart Parent Survey – Prenatal Version shows promise as a tool to capture outcomes of prenatal education programs.
