Conclusion Findings support the biological hypothesis of the importance of mode, timing of birth and breastfeeding in development of gut microbiota and immune system in early life. Spontaneous vaginal birth at 39+ weeks gestation with any exposure to breastmilk at birth minimises the risk of AGE hospital admission in early childhood.

**O-172**  INFANT FEEDING AND ANTI-TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS IN CHILDREN WITH SUBCLINICAL CELIAC DISEASE: THE GENERATION R STUDY

IIM Tromp, 1MAE Jansen, 1JC Kiefe-de Jong, 3WW Jaddoe, 4A Hofman, 4IC Escher, 4H Hooijkaas, 4HA Moll. Pediatrics/The Generation R Study Group, Erasmus University Medical Center, Rotterdam, Netherlands; 2Epidemiology, Erasmus University Medical Center, Rotterdam, Netherlands; 3The Generation R Study Group/Pediatrics/Immunology, Erasmus University Medical Center, Rotterdam, Netherlands; 4Pediatrics, Erasmus University Medical Center, Rotterdam, Netherlands.

Objectives To examine whether the timing of gluten introduction and breastfeeding duration are associated with subclinical celiac disease in children at the age of 6 years.

Methods This study was embedded in the Generation R study, a population-based prospective cohort study. Participants included 1679 Dutch children positive for HLA-DQ2/DQ8. Data on the timing of gluten introduction (<6 months vs. ≥6 months) and duration of breastfeeding (<6 months vs. ≥6 months) were obtained by questionnaire. Serum samples were analysed for anti-tissue transglutaminase (tTG) levels at age 6 years. Anti-tTG levels were categorised into negative (≤7 U/ml) and positive (>7 U/ml) levels. Positive anti-tTG levels were further categorised based on the ≥10 times upper limit of normal (ULN) levels of the test kit (>7–70 U/ml and >70 U/ml). Multivariable logistic regression analyses were performed.

Results Positive anti-tTG levels were found in 43 children of which 26 children had levels above the 10 times ULN (>70 IU/ml). The introduction of gluten from the age of 6 months onwards and breastfeeding for 6 months or longer were not significantly associated with positive anti-tTG levels. In addition, the timing of gluten introduction and duration of breastfeeding were not significantly associated with positive anti-tTG levels below and above the 10 times ULN.

Conclusions Delayed introduction of gluten beyond the age of 6 months does not increase the risk of subclinical CD. Also, breastfeeding for 6 months or longer does not decrease the risk of subclinical CD in children at 6 years of age.

**O-173**  EVALUATING THE POTENTIAL ROLE OF SMALL INTESTINE CONTRAST ULTRASONOGRAPHY IN PAEDIATRIC CROHN’S DISEASE: 5 YEAR EXPERIENCE IN A SINGLE CENTRE

1A Hafiz, 1S Kumar, 2C Alexakis, 1B Tzia, 2J Pitcher, 2R Pollak. 1Medical School, St George’s Hospital, London, UK; 2Department of Gastroenterology, St George’s Hospital, London, UK.

Background and aims Small intestine contrast ultrasonography (SICUS) is an emerging, non-invasive technique which accurately assesses small bowel lesions associated with Crohn’s disease (CD) in adult patients, without exposure to medical radiation. We report our 5 year experience in a paediatric cohort.

Methods Patients with suspected or established CD who underwent SICUS were identified and radiological findings collated. SICUS was compared to conventional transabdominal ultrasound (TUS), ileocolonoscopy and magnetic resonance enterography (MRE). Accuracy and agreement of SICUS in detecting small bowel lesions and CD-related complications was assessed using kappa (κ) coefficient statistics.

Results 93 patients (median age 16 years, range 2–20, 49 male) underwent SICUS; 58 had suspected and 35 established CD. In suspected CD, sensitivity and specificity of SICUS in detecting CD small bowel lesions were 81.82% and 100% and TUS 85.71% and 87.50%, respectively. In established CD, sensitivity and specificity of SICUS were 83.33% and 100% and TUS 80.00% and 100%, respectively. Agreement with ileocolonoscopy was fair for the presence of lesions (SICUS, κ=0.38, TUS, κ=0.31). Agreement between SICUS and ileocolonoscopy was good for detecting strictures (κ=0.66) with a sensitivity of 100% and specificity of 97.62%. Comparing SICUS and TUS with MRE, agreement for the presence of lesions was κ=0.63 and 0.53, respectively. Agreement between SICUS and MRE was good for detecting strictures (κ=0.77) and fair for assessing dilatation (κ=0.45).

Conclusions SICUS offers a promising radiation-free, low cost alternative for diagnosing and monitoring paediatric CD small bowel complications. Its wider use should be adopted.
